

Transversal Repositories

They contain components or tools shared by several domains or microservices of a project and do not represent a specific functionality.

Their function is to provide shared technical services, infrastructure, or processes that can be used by different parts of the system.

Domain vs. Transversal

A domain repository has its own rules and language, while a transversal repository is shared infrastructure.

- **Domain** = what the business does.
- **Transversal** = what several domains need to function.

For example: “register a sale” belongs to the Sales domain. In contrast, “receive and route HTTP requests” is the responsibility of an API Gateway.

The 4 Transversal Repositories

1

Infrastructure

Contains the configuration of shared infrastructure, such as the single database, Docker, networks, environment variables, etc.

2

API Gateway

It is the entry point to the system. It receives requests from the frontend and routes them to the corresponding microservice.

3

Worker

Processes background tasks, such as notifications and reports, ensuring a smooth and uninterrupted user experience.

4

Workflow

Contains the tools and configurations to automate processes. Example: CI/CD, tests, builds, deployments, and other repetitive tasks.
